Native Julia Solvers for Ordinary Differential Equations Boundary Value Problem: A GSoC proposal

Contents

1 The Project

1.1 Basic concepts for nonexperts

An ordinary differential equation (ODE) is an equality relationship between a function $y(x)$ and its derivatives, and an nth order ODE can be written as

$$F(x, y, y', \cdots, y^{(n)}) = 0$$

.

Physics and engineering often present ODE problems. Many physical phenomena can be reduced into an ODE. Newton's second law of motion, namely $F = ma$ can be rewritten into an

ODE as $m\frac{d^2x}{dt^2} = F(x)$, since a can depend on time. ODEs can be very difficult to solve. There are many cases in which an ODE does not have an analytical solution. Therefore, numerical methods need to be used to solve ODEs by approximating the solution. There are two kinds of ODE problems. One is initial value problem (IVP) and the other is boundary value problem (BVP). For instance, the ODE

$$m\frac{d^2x}{dt^2} = -kx(t)$$

describes the motion for a harmonic oscillator. If the initial position x_0 and initial velocity $\frac{dx_0}{dt}$ are known, then it is an IVP problem. If the condition at the "boundary" is known, for instance, initial position x_0 and final position x_1, then it is a BVP problem. My proposal is for the development of efficient and general-purpose BVP solvers for the Julia ecosystem.

1.1.1 Introduction

The project that I propose to work on in Google's Summer of Code project is the native Julia implementation of some BVP solving methods for ODE, namely, collocation method and shooting method.

1.2 Project Goals

1.2.1 Goal 1: Implement BVP related data structure

A data structure to describe the BVP problem, namely, "BVProblem". It contains the information

$$\begin{aligned}
&F(x, y, y', \cdots, y^{(n)}) = 0\\
&\text{domin: } x \in [a, b]\\
&\text{boundary condition: Dirichlet, Neumann, Robin.}
\end{aligned}$$

It can be defined by

$$\text{prob} = \text{BVProblem}(f, domin, bc)$$

.

```julia
abstract AbstractBVProblem{dType,bType,isinplace,F} <: DEProblem

type BVProblem{dType,bType,initType,F} <: AbstractBVProblem{dType,bType,F}
  f::F
  domin::dType
  bc::bType   #boundary condition
  init::initType
end

function BVProblem(f,domin,bc,init=nothing)
  BVProblem{eltype(domin),eltype(bc),eltype(init),typeof(f)}(f,domin,bc,init)
end
```

Also, I need to add a data structure for boundary conditions, which let users to define a boundary condition easily. The following is a template.

```julia
abstract AbstractBoundaryCondition

type DirichletBC <: AbstractBoundaryCondition; end
type NeumannBC <: AbstractBoundaryCondition; end
type RobinBC <: AbstractBoundaryCondition; end
```

1.2.2 Goal 2: Implement shooting method

The shooting method is a method that converts a BVP problem into an IVP problem and a root finding problem. Generally, the shooting method is efficient in simple problems because it does not need a discretization matrix. This reduces the memory overhead. The drawback is that even if the BVP problem is well-conditioned, the root finding problem that the BVP converted to can be ill-conditioned. Therefore, a more robust method like the collocation method is also needed, despite the fact that the shooting shooting method is easy to implement.

This is the my current implementation of the shooting method. I will work on to generalize it later, e.g. let user has the ability to input a ODE solver and a minimization algorithm.

```julia
function solve(prob::BVProblem; OptSolver=LBFGS())
  bc = prob.bc
  u0 = bc[1]
  len = length(bc[1])
  probIt = ODEProblem(prob.f, u0, prob.domin)
  function loss(minimizer)
    probIt.u0 = minimizer
    sol = DifferentialEquations.solve(probIt)
    norm(sol[end]−bc[2])
  end
  opt = optimize(loss, u0, OptSolver)
  probIt.u0 = opt.minimizer
  @show opt.minimum
  DifferentialEquations.solve(probIt)
end
```

1.2.3 Goal 3: Implement collocation method

The collocation method is the idea that a solution $y(x)$ of a ODE $F(x, y, y', \cdots, y^{(n)}) = 0$ can be approximated by a linear combination of basis functions.

$$y(x) \approx \hat{y}(x) = \phi_0 + \sum_{i=1}^{n} a_i \phi_i(x)$$

And the residual $R(x, a)$ can be written as

$$F(x, \hat{y}(x), \hat{y'}(x), \cdots, \hat{y}^{(n)}(x)) = R(x, a)$$

.

Collocation method forces the residual $R(x, a)$ to be 0 for n collocation points. There are different discretization methods in collocation method, and I am going to work on Simpson discretization, Gauss discretization, Radau discretization, and Lobatto discretization this summer. The “discretization” is really a matrix A that applies different quadrature rules e.g. Simpson's rule to a vector $\vec{x}$. It forms a sparse linear system $A\vec{x} = \vec{b}$ where $\vec{b}$ is known by the boundary condition and RHS of the ODE.

A quadrature rule is a numeric method to calculate a well-behaved define integral (no singularity). It uses the idea that a function $f(x)$ can be represented by multiplying an orthogonal polynomial $P(x)$ and another function $W(x)$.

$$f(x) = P(x) \cdot W(x)$$

Therefore, a define integral of a function F can be approximated by a linear combination of orthogonal polynomials p_i and their weights w_i.

$$F = \int_a^b f(x)\, dx = \int_a^b P(x)W(x) \approx \sum_{i=1}^{n} p_i(x) \cdot w_i(x)\, dx$$

1.3 Simpson Quadrature

Simpson's rule is a three-point Newton-Cotes quadrature rule. Its formula is

$$\int_a^b f(x)\,dx \approx \tfrac{b-a}{6}\left[f(a) + 4f\left(\tfrac{a+b}{2}\right) + f(b)\right].[1]$$

The error for the Simpson's rule is

$$\frac{1}{90}\left(\frac{b-a}{2}\right)^5 \left|f^{(4)}(\xi)\right|,$$

where the $\xi \in (a,b)$ by Lagrange error bound. [2]
Simpson's 3/8 rule is

$$\int_a^b f(x)\,dx \approx \tfrac{3h}{8}\left[f(x_0) + 3f(x_1) + 3f(x_2) + 2f(x_3) + 3f(x_4) + 3f(x_5) + 2f(x_6) + \ldots + f(x_n)\right],[3]$$

where $h = (b-a)/h$ and $x_i = a + ih$.

1.4 Gauss–Legendre quadrature

The Gauss–Legendre quadrature's weight is

$$w_i = \frac{2}{(1-x_i^2)\left[P_n'(x_i)\right]^2} = \frac{2\left(1-x_i^2\right)}{\left((n+1)\right)^2\left[P_{n+1}(x_i)\right]^2}[4]$$

1.5 Lobatto Quadrature

The Lobatto quadrature on the interval $[-1,1]$ is

$$\int_{-1}^1 f(x)\,dx = \frac{2}{n(n-1)}[f(1) + f(-1)] + \sum_{i=2}^{n-1} w_i f(x_i) + R_n, [5]$$

with the weights

$$w_i = \frac{2}{n(n-1)[P_{n-1}(x_i)]^2}, \qquad x_i \neq \pm 1.[5]$$

P_n is the nth order Legendre polynomial, and it can be written as

$$P_n(x) = 2^n \cdot \sum_{k=0}^{n} x^k \binom{n}{k}\binom{\frac{n+k-1}{2}}{n}.$$

1.6 Stretch Goals and Future Directions

1.6.1 Compatibility with the features of the common interface

There are many features in *JuliaDiffEq* common interface. They are listed in http://docs.juliadiffeq.org/latest/basics/common_solver_opts.html, and I plan to implement the following.

- Continuous output
- Singularity handling
- *Progressbars* for linear ODEs
- Adaptivity

1.6.2 Weighted residual method

Unlike the collocation method forces the residual to be zero at a finite number of collection points, the weighted residual method minimize the residual over the entire interval of integration.

1.7 Timeline

Pre-GSoC Unfortunately, I have to work on function of matrix (a.k.a. matrix function) in Julia Lab. I don't have much time to work on the GSoC project until it starts.

Community Bonding: May 5 (Start) - May 30

- Learn more about Julia's type system and the coding style in *JuliaDiffEq*.
- Get proficient in Git version control system.
- Learn more about the collocation method and optimization methods that will be used in the shooting method.
- Send a pull request.

Shooting Method: May 30 - June 15

- Design a general framework for BVP problems. (e.g. *BVProblem* and *BoundaryCondition* data structure.)
- Generalize shooting method.
- Test shooting method with some simple problems with analytical solutions.
- Learn more deeply about collocation methods.
- Send a pull request.

Discretization Algorithms: June 15 - July 10

- Design a basic framework for different types of discretization for solving BVP problems.
- Implement different kinds of discretization algorithms for collection methods.
- Optimize those discretization algorithms that are implemented with *SIMD* and some other techniques.
- Send a pull request.

Collocation Method: July 10 - July 31

- Implement the collocation method.
- Add more sophisticated testing BVP problems to test against the collocation method.
- Optimize the collocation method.
- Send a pull request.

Documentation: July 31 - August 15

- Write a documentation page for the BVP solvers that I have written.
- Add more tests for BVP problem and tune the algorithm.
- Send a pull request.

Review & Stretch Goals: August 15 - August 29 (End)

- Start to work on the stretch goals.
- Send a pull request.
- Review and test all the code that I have written in GSoC project.

1.8 Potential Hurdles

The potential hurdles I see are mostly because I have not worked in a big project like this before, and I may use some effort to be familiar with the coding style in *JuliaDiffEq* organization. I need to be proficient with Git. I also need to be more fluent in Julia's type system. I used to work in linear algebra which does not require much familiarity about the software engineering side.

1.9 Mentor

My mentor will be Christopher Rackauckas.

1.10 Julia Coding Demo

Here are my code that is written in Julia.
https://github.com/JuliaDiffEq/BoundaryValueDiffEq.jl
https://github.com/obiajulu/ODE.jl/tree/radau Worked with with Joseph Obiajulu.
https://github.com/YingboMa/BVP.jl
https://github.com/YingboMa/Funm.jl

1.11 About me

My name is Yingbo Ma, and I am currently a senior in Lexington Public High School. I got admitted by University of California, Irvine (UCI). I am interested in mathematics and physics and willing to learn new things about them. I worked with Joseph Obiajulu on *ODE.jl* last summer in MIT Julia Lab. I still go to Julia Lab regularly now, and now I am working on fixing the *logm* function in Julia base.

GitHub: YingboMa

2 Summer Logistics

Work hours: I expect to be able to work over 35 hours per week though this summer. I do not have much other thing to do besides working in this project, so I can put most of my attention in this project. Over all I am able to put 400-500 hours into this project.
